

# He<sup>+</sup> Lyman continuum in low-metallicity starbursts

Manfred W. Pakull

Observatoire Astronomique de Strasbourg

Galaxies meet GRB at Cabo de Gata, 23-27. Sept. 2013

# HeII $\lambda 4686$ emission in HII galaxies

Bergeron (1977) noted  $\lambda 4686$  emission in IZw18

Often 2 components:

- B=broad : due to WR stars
- N=narrow (nebular): requires ionizing photons with  $h\nu > 54$  eV (He+ Ly cont.)

also: high-excitation spectra  
i.e. high [OIII]/Hbeta ratio

Lopez-Sanchez & Esteban 2010:

# HeII $\lambda 4686$ emission in HII galaxies

Bergeron (1977) noted  $\lambda 4686$  emission in IZw18

Often 2 components:

- **B=broad** : due to WR stars
- **N=narrow (nebular)**: requires ionizing photons with  $h\nu > 54$  eV (He+ Ly cont.)

also: high-excitation spectra  
i.e. high [OIII]/Hbeta ratio

Lopez-Sanchez & Esteban 2010:

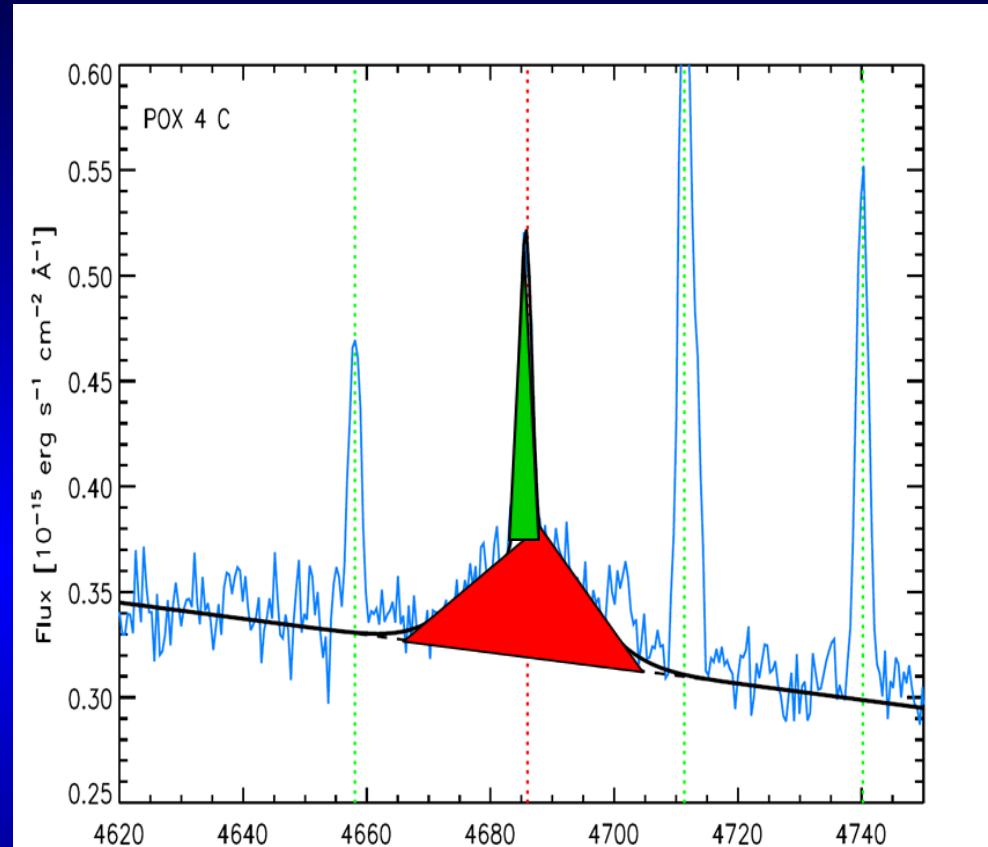

# HeII $\lambda 4686$ emission in HII galaxies

Bergeron (1977) noted  $\lambda 4686$  emission in IZw18

Often 2 components:

- **B=broad** : due to WR stars
- **N=narrow** (nebular): requires ionizing photons with  $h\nu > 54$  eV (He+ Ly cont.)

also: high-excitation spectra  
i.e. high [OIII]/Hbeta ratio

Lopez-Sanchez & Esteban 2010:

POX 4: **N/B** = 0.6

# HeII $\lambda 4686$ emission in HII galaxies

Bergeron (1977) noted  $\lambda 4686$  emission in IZw18

Often 2 components:

- B=broad : due to WR stars
- N=narrow (nebular): requires ionizing photons with  $h\nu > 54$  eV (He+ Ly cont.)  
→ HeIII region

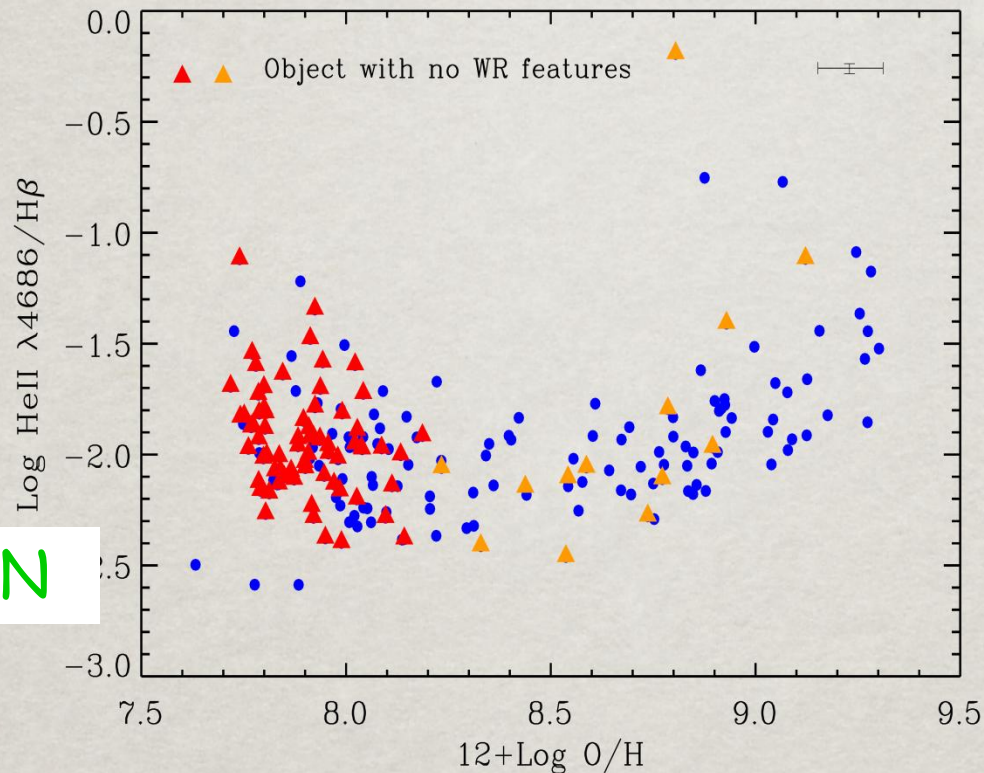

also: high-excitation spectra  
i.e. high [OIII]/Hbeta ratio

Lopez-Sanchez & Esteban 2010:

POX 4:  $N/B = 0.6$

# Narrow HeII 4686 emission in HII galaxies

Z

Guseva+00; Brinchman+09,  
Shirazi+12:

high Z: 4686N and 4686B  
are linked;

low Z: 4686N not associated  
with 4686B WR features

-> other ion. mechanism (?)

At Z ~ solar: All have WR features

At Z ~ solar/10: ~30% have.

# Sources of He+ Ly C ( $h\nu > 54\text{eV}$ )

- hot MS \*\*\* ? ( $T_{\text{eff}} > 70,000\text{ K}$ ),
- Massive X-ray binaries ?
- population III stars ?
- hidden AGN ?
- fast shocks  $v_s > 300\text{ km/s}$ ; in isolated SNR, not wind bubbles !
- Hot Wolf-Rayet stars ? WO, WNE, H-rich WN
- rapid rotators with chemically homogenous evolution ?
- Pec. massive binary evol. (N44C, some M33 objects ) ?

# HeIII regions around local WRs

-> 1990: two HeIII regions around WO stars: WR102 and IC1613\_S3  
Terlevich: explanation of AGN by such hot (WOs): 'Warmers'

IAU 143: 2 WNEs in LMC (Br2, Br40a), 1 WNe in SMC (AB7) ionize HeIII regions, and not all WO's are "Warmers" (Niemela+1991; Pakull+1991), and no HeIII around WCs!

More recently HeIII regions around faint H-rich WNs in the SMC  
WR10, WR9 (Pakull 2007; 2013)

MW: 1/300

LMC: 2/150      WRs ionize HeIII regions

SMC: 3/12

i.e. fraction of "Warmers" increases with decreasing Z!

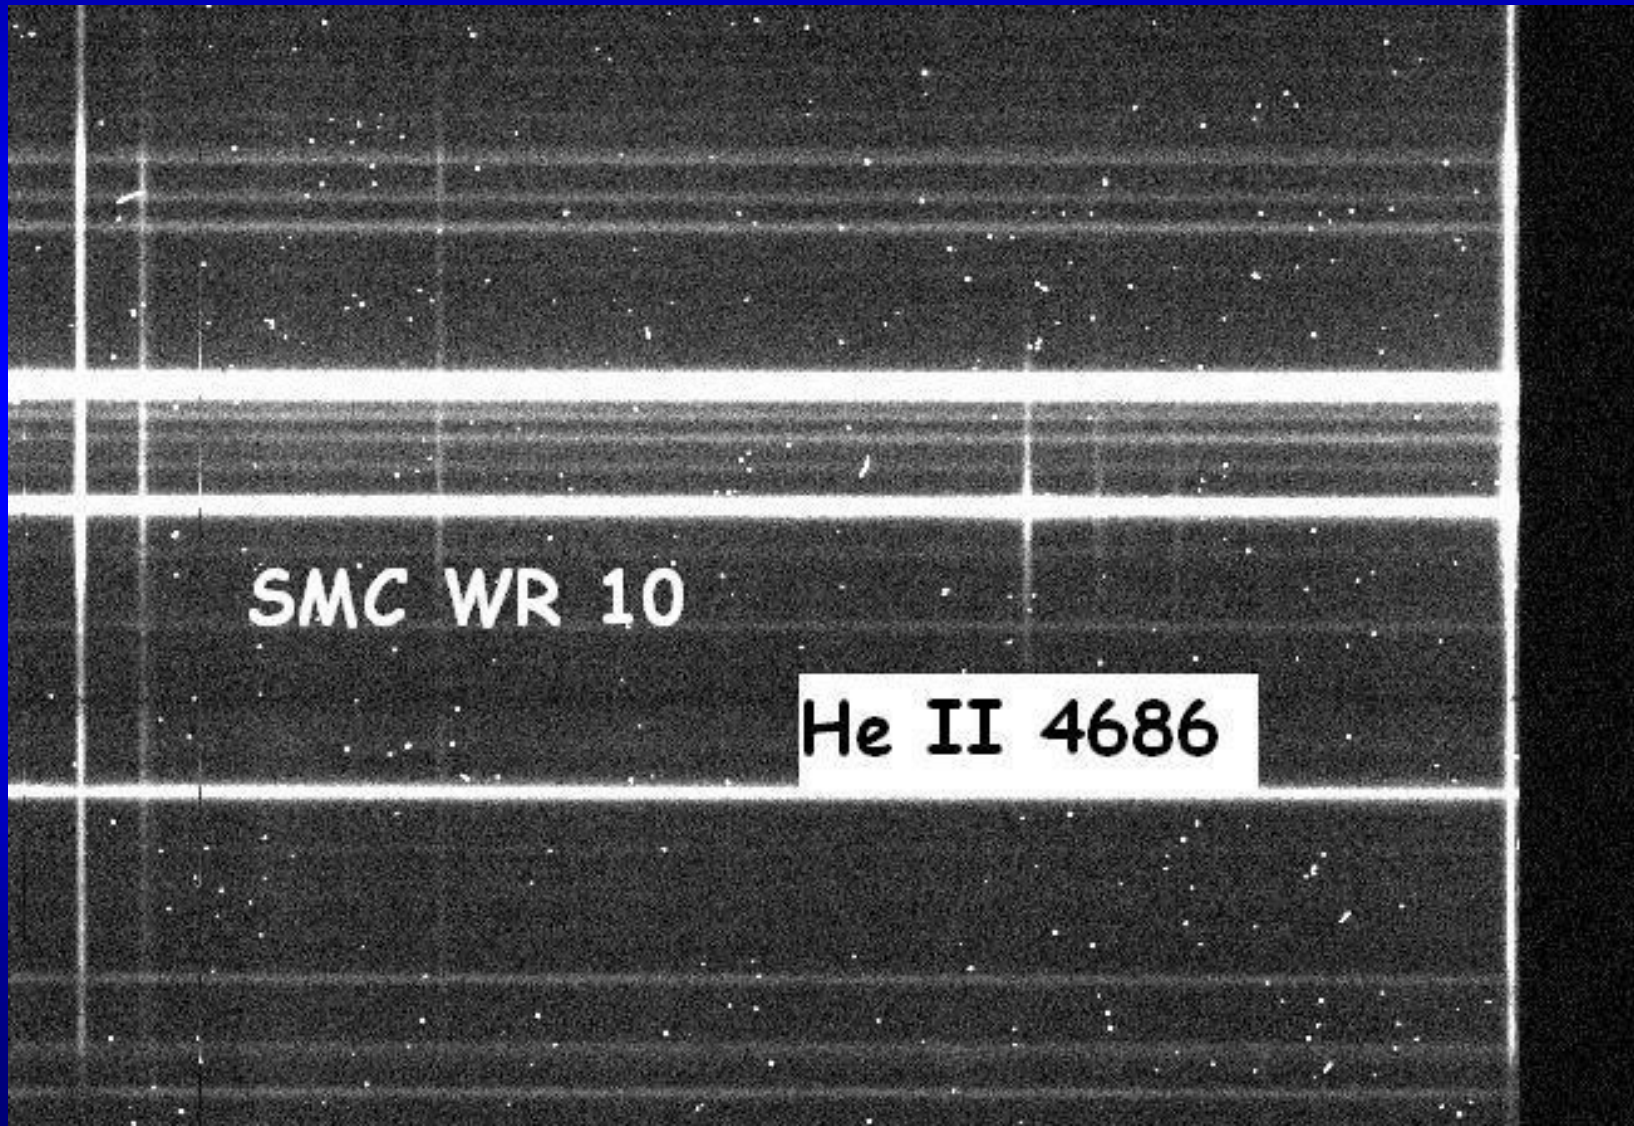

# SMC WR 10 in NGC 249

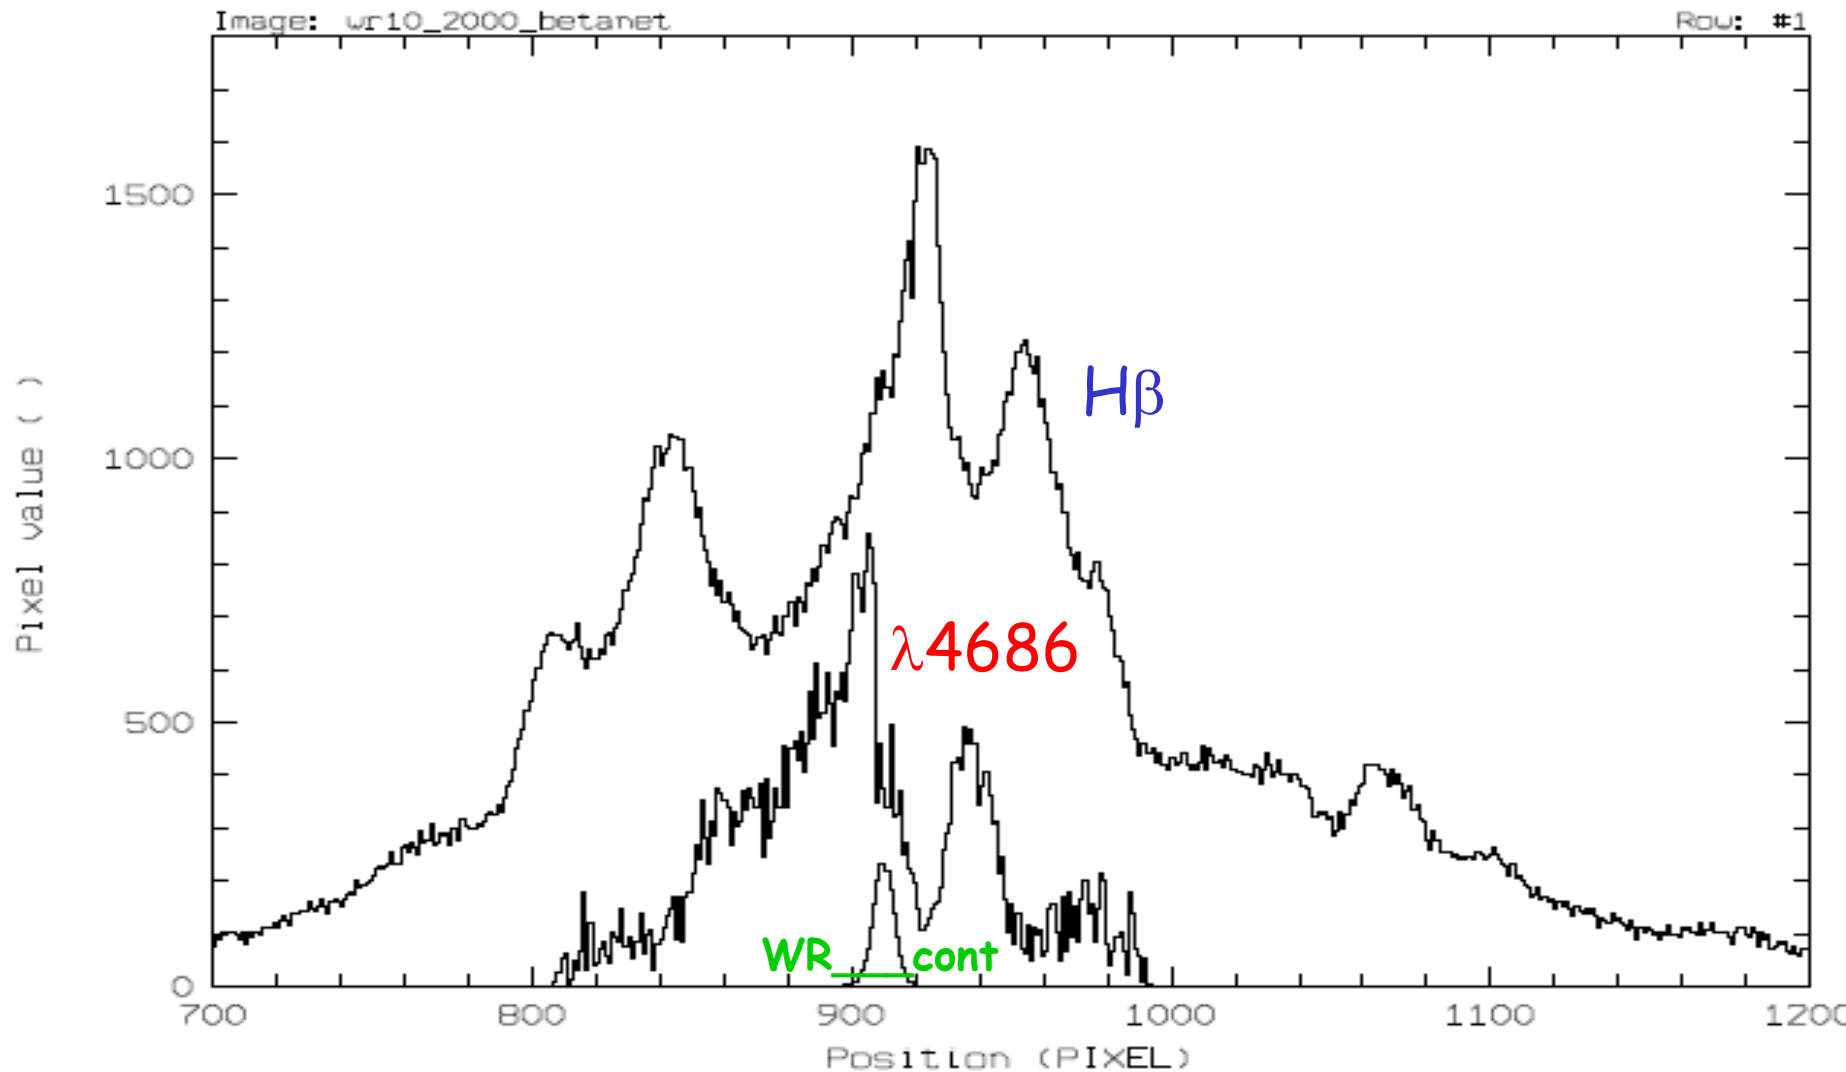

ESO H $\alpha$

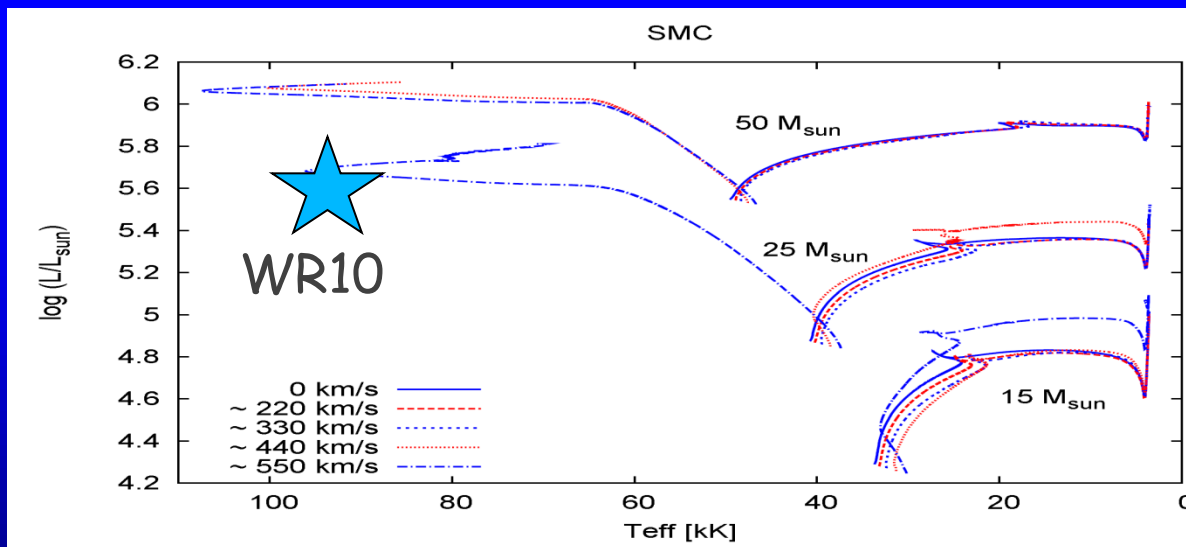

(Pakull 2007) Spitzer IR

# SMC WR 10: 2d spectrum

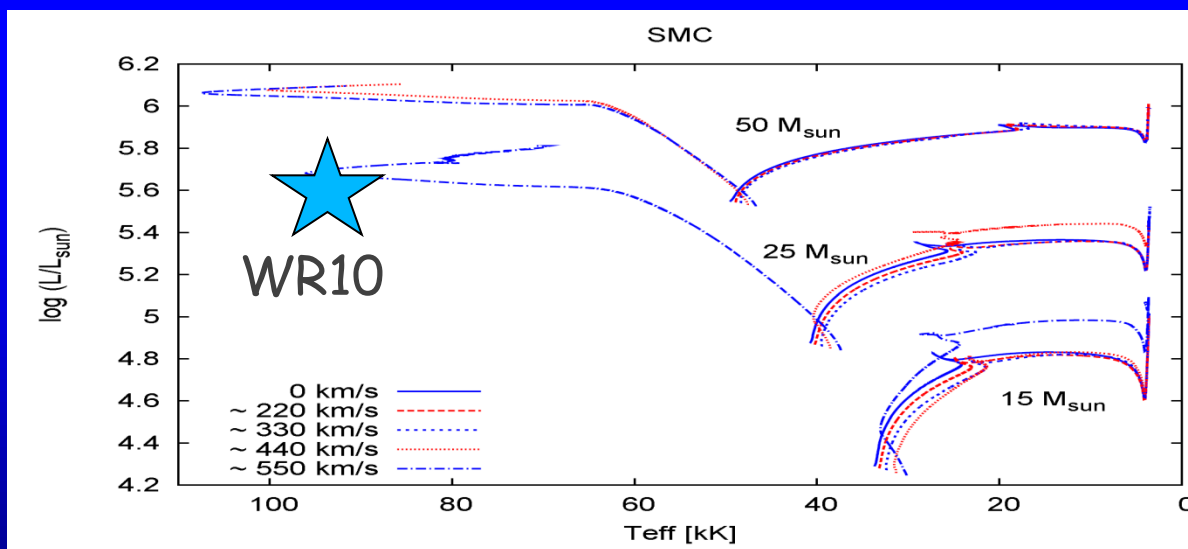

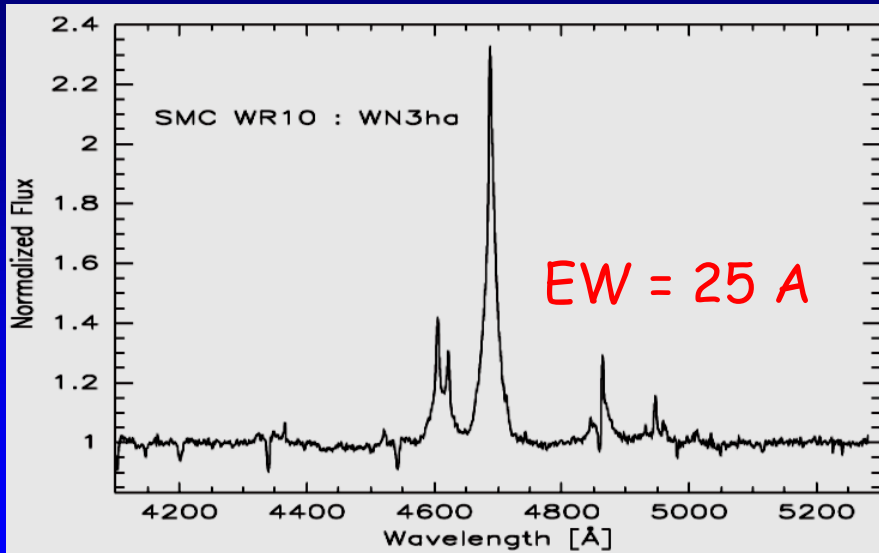

# SMC WR 10 HeIII region

Foellmi 2005/6 :  
 WR10: single star; weak  
 lines; hydrogen present

Brott+ 2011: SMC abund. with rot. mixing

Foellmi 2005/6 :  
WR10: single star; weak  
lines; hydrogen present

**Problem:**  
 **$V_{\text{rot}} \ll 550 \text{ km/s}$**

Brott+ 2011: SMC abund. with rot. mixing

# Kehrig+ 2011: HeIII regions in M33

M33 NOAO LGS

H $\alpha$  = R. (red) [SII] = G (green) [OIII] = B (blue)

Highly excited (blue) nebula  $\rightarrow$  mostly around WR stars (WN)

# Outlying HII region MA1 in M33

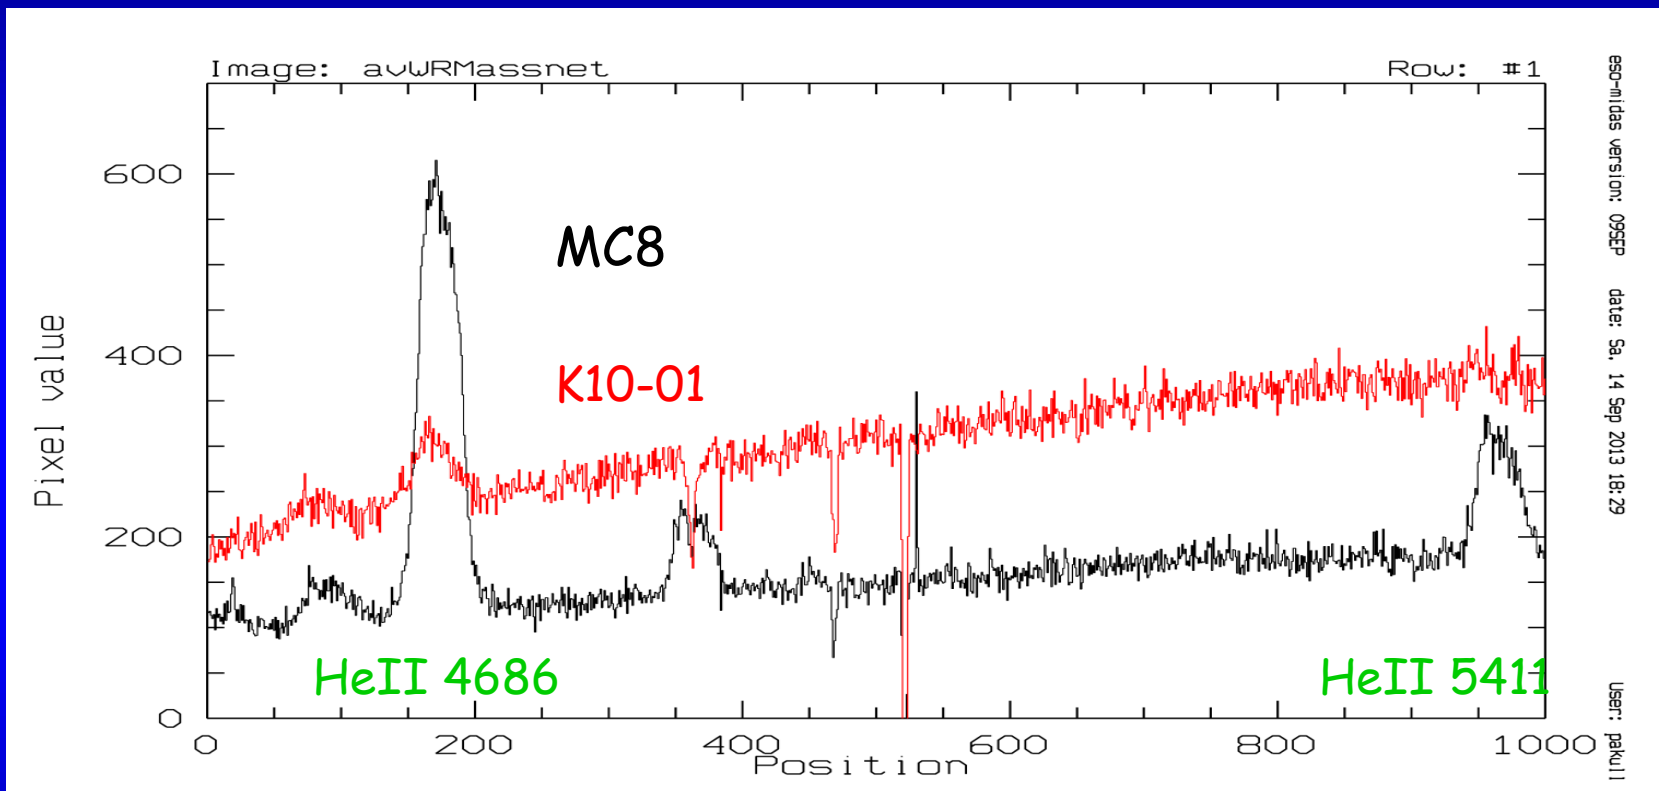

NOAO

Kehrig+: HeII 4686net

# WR stars in MA1

MC8	$\lambda 4686$ : EW = 110 A	N/B = 0
K10-01	= 12 A	= 12

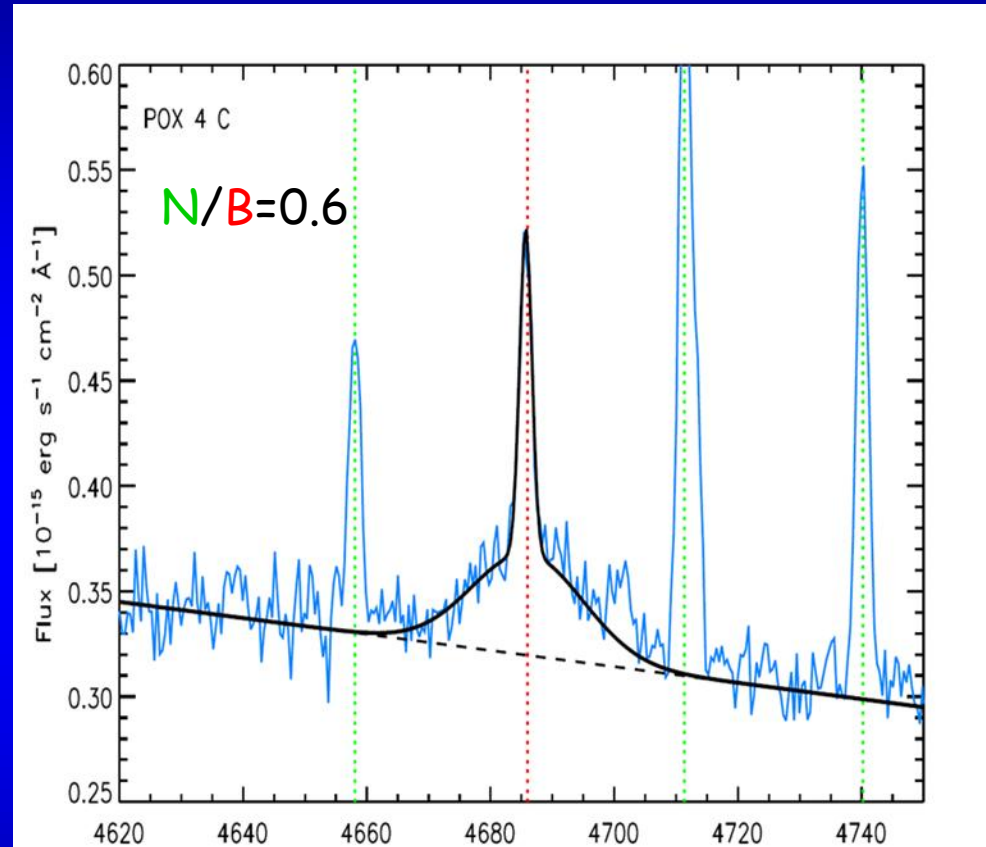

# HeII4686 N/B in some local Warmers

4686 N/B =	}	6.8 Br2 LMC
		8.0 WR7 SMC
		5.0 WR10 SMC
		1.7 *14 M33
		12 K10-01 M33

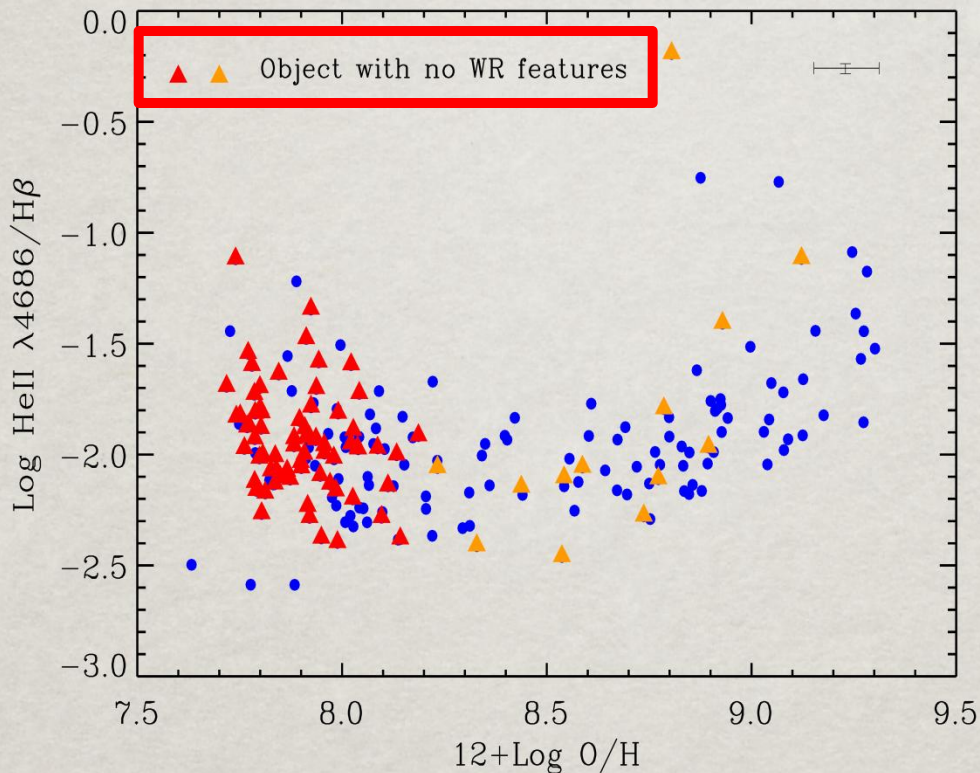

→ Relatively narrow range suggesting similar atmosphere conditions

# Further away from home ...

Only the narrow  
component visible  
if  $N/B > 2 - 3$

# Narrow HeII 4686 emission in HII galaxies

At  $Z \sim$  solar: All have WR features

At  $Z \sim$  solar/10:  $\sim 30\%$  have.

Guseva+00; Brinchman+09,  
Shirazi+12

At low  $Z$ : many HIIG lack  
WR features  
\* evol. fewer WR expected

Probably ionisation by  
'Warmers' with high  $N/B$

# WR model atmospheres

Schmutz et al 1992: spectrum mainly determined by:

$$T_c, R_t \sim R^* (v/\dot{M})^{2/3}$$

Hamann & Gräfener (2004)

WR model grid **PoWR**

# WR star models: dependence on mass loss rate (or $R_t$ )

Smith+2002; Crowther+2009

If we decrease mass loss rate, wind abruptly becomes optically thin for  $\lambda < 228 \text{ \AA}$  ( $h\nu > 4\text{Ryd}$ ), i.e. emission of **He+ LyCont**  $\rightarrow$  **HeIII region**

# WR model atmospheres

Schmutz et al 1992: spectrum mainly determined by:

$$T_c, R_t \sim R^* (v/\dot{M})^{2/3}$$

Hamann & Gräfener (2004)

WR model grid **PoWR**

Comparison of PoWR and CMFGEN (Smith et al 2002) for He+ LyC of weak wind WN reveals factor 10 difference!

possibly log g effect?

model:  
weak He+ LyC

 - region of highest ionisation

# What have we learned ?

- Some rare hot Wolf-Rayet stars with weak winds emit strong He+ LyC : 'Warmers'; HeII $\lambda$ 4686 : N/B ~2-10.
- Distant Warmers can be detected through 4686N
- The fraction of Warmers increases with decreasing Z
- We don't yet understand evolution of WN Warmers; chemically homogeneous evolution ?
- POWR and CEMGEN WR models with same  $T_c$  and (low)  $\dot{M}$  differ in He+ LyC flux by 10; log g effect ?
- Don't trust spectral evolutionary models for  $\lambda < 228 \text{ \AA}$  !
- Broad slit (imaging) spectra can be useful, too.
